Received July 15, 2008; Revised September 18, 2008

The memristor has attracted phenomenal worldwide attention since its debut on 1 May 2008 issue of Nature in view of its many potential applications, e.g. super-dense nonvolatile computer memory and neural synapses. The Hewlett-Packard memristor is a passive nonlinear two-terminal circuit element that maintains a functional relationship between the time integrals of current and voltage, respectively, viz. charge and flux. In this paper, we derive several nonlinear oscillators from Chua’s oscillators by replacing Chua’s diodes with memristors.

Keywords: Memristor; memristive devices; memristive systems; charge; flux; Chua’s oscillator; Chua’s diode; learning; neurons; synapses; Hodgkin-Huxley; nerve membrane model.

1. Memristors

In a seminal paper [Strukov et al., 2008] which appeared on 1 May 2008 issue of Nature, a team led by R. Stanley Williams from the Hewlett-Packard Company announced the fabrication of a nanometer-size solid-state two-terminal device called the memristor, a contraction for memory resistor, which was postulated in [Chua, 1971; Chua & Kang, 1976]. This passive electronic device has generated unprecedented worldwide interest\(^1\) because of its potential applications [Tour & He, 2008; Johnson, 2008] in the next generation computers and powerful brain-like “neural” computers. One immediate application offers an enabling low-cost technology for non-volatile memories\(^2\) where future computers would turn on instantly without the usual “booting time”, currently required in all personal computers.

More than one million Google hits were registered as of June 1, 2008.

The Hewlett-Packard memristor is a tiny nano, passive, two-terminal device requiring no batteries. Memristors characterized by a nonmonotonic constitutive relation are called active memristors in this paper because they require a power supply.

The HP memristor shown in Fig. 1 is a passive two-terminal electronic device described by a nonlinear constitutive relation

\[ v = M(q)i, \quad \text{or} \quad i = W(\varphi)v, \] (1)

between the device terminal voltage \(v\) and terminal current \(i\). The two nonlinear functions \(M(q)\) and \(W(\varphi)\), called the memristance and memductance, respectively, are defined by

\[ M(q) \triangleq \frac{d\varphi(q)}{dq}, \] (2)

and

\[ W(\varphi) \triangleq \frac{dq(\varphi)}{d\varphi}, \] (3)

representing the slope of a scalar function \(\varphi = \varphi(q)\) and \(q = q(\varphi)\), respectively, called the memristor constitutive relation.

\(^1\)More than one million Google hits were registered as of June 1, 2008.

\(^2\)The Hewlett-Packard memristor is a tiny nano, passive, two-terminal device requiring no batteries. Memristors characterized by a nonmonotonic constitutive relation are called active memristors in this paper because they require a power supply.
A memristor characterized by a differentiable \( q - \varphi \) (resp. \( \varphi - q \)) characteristic curve is passive if, and only if, its small-signal memristance \( M(q) \) (resp. small-signal memductance \( W(\varphi) \)) is non-negative; i.e.,

\[
M(q) = \frac{d\varphi(q)}{dq} \geq 0 \quad \text{resp.} \quad W(\varphi) = \frac{dq(\varphi)}{d\varphi} \geq 0
\]

(see [Chua, 1971]). In this paper, we assume that the memristor is characterized by the "monotone-increasing" and "piecewise-linear" nonlinearity shown in Fig. 2, namely,

\[
\varphi(q) = bq + 0.5(a - b)(|q + 1| - |q - 1|), \quad \text{(5)}
\]

or

\[
q(\varphi) = d\varphi + 0.5(c - d)(|\varphi + 1| - |\varphi - 1|), \quad \text{(6)}
\]

where \( a, b, c, d > 0 \). Consequently, the memristance \( M(q) \) and the memductance \( W(\varphi) \) in Fig. 2 are defined by

\[
M(q) = \frac{d\varphi(q)}{dq} = \begin{cases} a, & |q| < 1, \\ b, & |q| > 1, \end{cases}
\]

(7)

and

\[
W(\varphi) = \frac{dq(\varphi)}{d\varphi} = \begin{cases} c, & |w| < 1, \\ d, & |w| > 1, \end{cases}
\]

(8)

respectively. Since the instantaneous power dissipated by the above memristor is given by

\[
p(t) = M(q(t))i(t)^2 \geq 0,
\]

(9)

or

\[
p(t) = W(\varphi(t))v(t)^2 \geq 0,
\]

(10)

the energy flow into the memristor from time \( t_0 \) to \( t \) satisfies

\[
\int_{t_0}^{t} p(\tau)d\tau \geq 0,
\]

(11)

for all \( t \geq t_0 \). Thus, the memristor constitutive relation in Fig. 2 is passive.

Consider next the two-terminal circuit in Fig. 3, which consists of a negative resistance\(^3\) (or a negative conductance) and a passive memristor. If the two-terminal circuit has a flux-controlled

\[^3\text{The negative resistance or conductance can be realized by a standard op amp circuit, powered by batteries.}\]
Two-term inal circuit

![Two-terminal circuit](image)

Active memristor

Fig. 3. Two-terminal circuit which consists of a memristor and a negative conductance \(-G\) (or a resistance \(-R\)).

\[
q(\varphi) = \int i(\tau)d\tau = \int (i_1(\tau) + i_2(\tau))d\tau = \int (W(\varphi)v - Gv)d\tau = \int (W(\varphi) - G)v d\tau
\]

\[
= \int (W(\varphi) - G)d\varphi \left( \frac{d\varphi}{d\tau} = v \right) = d\varphi + 0.5(c - d)(|\varphi + 1| - |\varphi - 1|) - G\varphi = (d - G)\varphi + 0.5(c - d)(|\varphi + 1| - |\varphi - 1|),
\]

where we assumed that \(q(\varphi)\) is a continuous function satisfying \(q(0) = 0\) and \(G > 0\). Thus, the small signal memductance \(\overline{W}(\varphi)\) of this two-terminal circuit is given by

\[
\overline{W}(\varphi) = \frac{dq(\varphi)}{d\varphi} = \begin{cases} c - G, & |w| < 1, \\ d - G, & |w| > 1. \end{cases}
\]

If \(c - G < 0\) or \(d - G < 0\), then the instantaneous power does not satisfy

\[
p(t) = \overline{W}(\varphi(t))v(t)^2 \geq 0,
\]

Fig. 4. \(\varphi - q\) characteristic of the two-terminal circuit.
for all \( t > 0 \). In this case, there exists \( \varphi(t_0) = \varphi_0 \) and

\[
\int_{t_0}^{t} p(\tau) d\tau < 0,
\]

for all \( t \in (t_0, t_1) \). Thus, the two-terminal circuit in Fig. 3 can be designed to become an active device, and can be regarded as an “active memristor”. We illustrate two kinds of characteristic curves in Fig. 4. Similar characteristic curves can be obtained for charge-controlled memristors. In this paper, we design several nonlinear oscillators using active or passive memristors.

2. Circuit Laws

In this section, we review some basic laws for electrical circuits. Recall first the following principles of conservation of charge and flux [Chua, 1969]:

- Charge and flux can neither be created nor destroyed. The quantity of charge and flux is always conserved.

We can restate this principle as follows:

- Charge \( q \) and voltage \( v_C \) across a capacitor cannot change instantaneously.
- Flux \( \varphi \) and current \( i_L \) in an inductor cannot change instantaneously.

Applying this principle to the circuit, we can obtain a relation between the two fundamental circuit variables: the “charge” and the “flux”. However, we usually use the other fundamental circuit variables, namely the “voltage” and the “current” by applying the following Kirchhoff’s circuit laws [Chua, 1969]:

- The algebraic sum of all the currents \( i_m \) flowing into the node is zero:

\[
\sum_m i_m = 0.
\]

(16)

- The algebraic sum of branch voltages \( v_n \) around any closed circuit is zero:

\[
\sum_n v_n = 0.
\]

(17)

They are a pair of laws that result from the conservation of charge and energy in electrical circuits. If we apply the Kirchhoff’s circuit laws to a memristive circuit, we need the four fundamental circuit variables, namely the voltage, current, charge, and flux to describe their dynamics, because the relation between current \( i \) and voltage \( v \) of the memristor is defined by Eq. (1).

If we integrate the Kirchhoff’s circuit laws with respect to time \( t \), we would obtain the relation on the conservation of charge and flux:

\[
\sum m q_m = 0,
\]

(18)

and

\[
\sum n \varphi_n = 0.
\]

(19)

where \( q_m \) and \( \varphi_n \) are defined by

\[
q_m = \int_{-\infty}^{t} i_md\tau,
\]

(20)

and

\[
\varphi_n = \int_{-\infty}^{t} v_n d\tau,
\]

(21)

respectively.

The relationship between voltage \( v \) and current \( i \) for the four fundamental circuit elements is given by

- Capacitor

\[
C \frac{dv}{dt} = i
\]

(22)

- Inductor

\[
L \frac{di}{dt} = v
\]

(23)

- Resistor

\[
v = Ri
\]

(24)

- Memristor

\[
v = M(q)i \quad \text{or} \quad i = W(\varphi)
\]

(25)

Using these relations and the Kirchhoff’s circuit laws, we can describe the dynamics of electrical circuits.

Integrating Eqs. (22)-(25) with respect to time \( t \), we obtain the following equations:

- Capacitor

\[
q = Cv
\]

(26)

- Inductor

\[
\varphi = Li
\]

(27)

- Resistor

\[
\varphi = Rq
\]

(28)
Memristor

\[ \varphi = \int M(q) dq \quad \text{or} \quad q = \int W(\varphi) d\varphi \]  

(29)

where \( q = \int_{-\infty}^{t} idt \) and \( \varphi = \int_{-\infty}^{t} vdt \). They provide the relationship between Eqs. (16)-(17) and Eqs. (18)-(19).

3. Memristor-Based Canonical Oscillators

Chua's circuit in Fig. 5 is the simplest electronic circuit exhibiting chaotic behavior [Madan, 1993]. It is well known that the canonical Chua's oscillator [Chua & Lin, 1990] in Fig. 6 also has a chaotic attractor. In this section, we design a nonlinear oscillator by replacing the "Chua's diode" in the canonical Chua's oscillator with a memristor characterized by a "monotone-increasing" and "piecewise-linear" nonlinearity.

3.1. A fourth-order canonical memristor oscillator

Consider the canonical Chua's oscillator in Fig. 6. If we replace the Chua's diode in Fig. 6 with a flux-controlled memristor, we would obtain the circuit of Fig. 7. Its dual circuit\(^4\) can be easily obtained by using a charge-controlled memristor (see Fig. 8).

Applying Kirchhoff's circuit laws to the nodes \( A, B \) and the loop \( C \) of the circuit in Fig. 9, we obtain

\[ \begin{cases} 
  i_1 = i_3 - i, \\
  v_3 = v_2 - v_1, \\
  i_2 = -i_3 + i_4. 
\end{cases} \]  

(30)

Integrating Eq. (30) with respect to time \( t \), we get a set of equations which define the relation among two fundamental circuit variables, namely, the charge

\(^4\) A pair of circuits \( N \) and \( N' \) are dual if the equations of the two circuits are identical, after a trivial change of symbols. For more details, see [Chua, 1969].
and the flux:

\[
\begin{align*}
q_1 &= q_3 - q(\varphi), \\
q_3 &= \varphi_2 - \varphi_1, \\
q_2 &= -q_3 + q_4,
\end{align*}
\]

where

\[
\begin{align*}
q_1 &= \int_{-\infty}^{t} i_1(t)dt, \\
q_2 &= \int_{-\infty}^{t} i_2(t)dt, \\
q_3 &= \int_{-\infty}^{t} i_3(t)dt, \\
q_4 &= \int_{-\infty}^{t} i_4(t)dt, \\
q &= \int_{-\infty}^{t} i(t)dt,
\end{align*}
\]

Thus, \((q_1, q_2, \varphi, \varphi_3)\) can be chosen to be the independent variables, namely, the charge of the capacitors \(C_1, C_2\), and the flux of the inductor \(L\) and the memristor, respectively.

From Eq. (30) (or differentiating Eq. (31) with respect to time \(t\)), we obtain a set of four first-order differential equations, which define the relation among the four circuit variables \((v_1, v_2, i_3, \varphi)\):

\[
\begin{align*}
C_1 \frac{dv_1}{dt} &= i_3 - W(\varphi)v_1, \\
L \frac{di_3}{dt} &= v_2 - v_1, \\
C_2 \frac{dv_2}{dt} &= -i_3 + Gv_2, \\
\frac{d\varphi}{dt} &= v_1,
\end{align*}
\]

Note that the two kinds of independent variables are related by

\[
(q_1, q_2, \varphi, \varphi_3) \leftrightarrow (v_1, v_2, \varphi, i_3)
\]

Thus, Eq. (35) can be recast into the following set of differential equations using only charge and flux as variables:

\[
\begin{align*}
\frac{dq_1}{dt} &= \frac{\varphi_3}{L} - \frac{W(\varphi)q_1}{C_1}, \\
\frac{dq_2}{dt} &= -\frac{\varphi_3}{L} + \frac{Gq_2}{C_2}, \\
\frac{dq_3}{dt} &= \frac{q_2}{C_2} - \frac{q_1}{C_1}, \\
\frac{dq_4}{dt} &= Gv_2, \\
\frac{d\varphi}{dt} &= \frac{dq(\varphi)}{d\varphi}.
\end{align*}
\]
We next study the behavior of this circuit. Equation (35) can be transformed into the form
\[
\begin{align*}
\frac{dx}{dt} &= \alpha(y - W(w)x), \\
\frac{dy}{dt} &= z - x, \\
\frac{dz}{dt} &= -\beta y + \gamma z, \\
\frac{dw}{dt} &= x,
\end{align*}
\] (39)
where \(x = v_1, y = i_3, z = v_2, w = \varphi, \alpha = 1/C_1, \beta = 1/C_2, \gamma = C/C_2, L = 1, \) and the piecewise-linear functions \(q(w)\) and \(W(w)\) are given by
\[
q(w) = bw + 0.5(a - b)(|w + 1| - |w - 1|),
\]
\[
W(w) = \begin{cases} a, & |w| < 1, \\ b, & |w| > 1, \end{cases}
\]
respectively, where \(a, b > 0\). Note that the uniqueness of solutions for Eq. (39) cannot be guaranteed since \(W(w)\) is discontinuous if \(a \neq b\). If we set \(\alpha = 4, \beta = 1, \gamma = 0.65, a = 0.2, \) and \(b = 10, \) our computer simulation shows that Eq. (39) has a chaotic attractor as shown in Fig. 10. By calculating the Lyapunov exponents from sampled time series, we found that this chaotic attractor has one positive Lyapunov exponent.

\[\text{Fig. 10. Chaotic attractor of the canonical Chua's oscillator with a flux-controlled memristor.}\]

\(^{5}\text{We used the fourth-order Runge-Kutta method for integrating the differential equations.}\)
Lyapunov exponent $\lambda_1 \approx 0.27$. Furthermore, the divergence of the vector field

$$\text{div}(X) = -\alpha W(w) + \gamma = -4W(w) + 0.65$$

is negative. It follows that the Lebesgue measure of this chaotic attractor is zero, and at least one Lyapunov exponent must be negative.\(^7\)

The equilibrium state of Eq. (39) is given by set

$$A = \{(x, y, z, w) | x = y = z = 0, w = \text{constant} \}$$

which corresponds to the $w$-axis. The Jacobian matrix $D$ at this equilibrium set is given by

$$D = \begin{bmatrix} -\alpha W(w) & \alpha & 0 & 0 \\ -1 & 0 & 1 & 0 \\ 0 & -\beta & \gamma & 0 \\ 1 & 0 & 0 & 0 \end{bmatrix},$$

and its characteristic equation is given by

$$\rho^4 + (\alpha W(w) - \gamma)\rho^3 + (\beta + \alpha - \alpha\gamma W(w))\rho^2 + \alpha(\beta W(w) - \gamma)\rho = 0.$$  \hspace{1cm} (43)

The four eigenvalues $\rho_i$ ($i = 1, 2, 3, 4$) of the equilibrium state $(0, 0, 0, w)$ can be written as

$$\rho_{1,2} \approx -0.267093 \pm i 2.148, \quad \rho_3 \approx 0.384186, \quad \rho_4 = 0, \quad \text{for } |w| < 1,$$

$$\rho_{1,2} \approx 0.274905 \pm i 0.928318, \quad \rho_3 \approx -39.8998, \quad \rho_4 = 0, \quad \text{for } |w| > 1.$$  \hspace{1cm} (44)

Thus, they are characterized by an unstable saddle-focus except for the zero eigenvalue. Furthermore, Eq. (39) can be transformed into the form

$$\frac{d^3 z}{dt^3} + (\alpha W(w) - \gamma)\frac{dz}{dt} + (\beta + \alpha - \alpha\gamma W(w))\frac{dz}{dt} + \alpha(\beta W(w) - \gamma)z = 0.$$  \hspace{1cm} (45)

If we substitute

$$u(t) = \int_0^t z(t)dt + u_0,$$  \hspace{1cm} (46)

into Eq. (45), we would obtain a fourth-order differential equation in the variable $u$; namely,

$$\frac{d^4 u}{dt^4} + (\alpha W(w) - \gamma)\frac{d^2 u}{dt^2} + (\beta + \alpha - \alpha\gamma W(w))\frac{d^2 u}{dt^2} + \alpha(\beta W(w) - \gamma)\frac{du}{dt} = 0,$$  \hspace{1cm} (47)

where

$$w(t) = \frac{\beta u - \gamma \frac{du}{dt} + \frac{d^2 u}{dt^2}}{\beta} + w_0.$$  \hspace{1cm} (48)

Here, $u_0$ and $w_0$ are constants. Thus, its characteristic equation also has a zero eigenvalue.

Consider next the fourth-order oscillator in Fig. 11 obtained by removing a resistor from the circuit of Fig. 7. The circuit equation can be written as

$$C_1 \frac{dv_1}{dt} = i_3 - W(\varphi)v_1,$$

$$L \frac{di_3}{dt} = v_2 - v_1,$$

$$C_2 \frac{dv_2}{dt} = -i_3,$$

$$\frac{dv_1}{dt} = v_1,$$  \hspace{1cm} (49)

Equation (35) can be transformed into the form

$$\frac{dx}{dt} = \alpha(y - W(w)x),$$

$$\frac{dy}{dt} = -\xi(x + z),$$

$$\frac{dz}{dt} = \beta y,$$

$$\frac{dw}{dt} = x.$$  \hspace{1cm} (50)

Fig. 11. A fourth-order oscillator with a flux-controlled memristor.

\(^6\)We used the software package MATDS [Govorkhin, 2004] to calculate the Lyapunov exponents.

\(^7\)Note that if the system is a flow, one Lyapunov exponent is always zero, which corresponds to the direction of the flow.
where \( x = v_1, y = i_3, z = -v_2, w = \varphi, \alpha = 1/C_1, \beta = 1/C_2, \xi = 1/L, \) and the piecewise-linear functions \( q(w) \) and \( W(w) \) are given by

\[
q(w) = bw + 0.5(a-b)(|w+1|-|w-1|),
\]
\[
W(w) = \frac{dq(w)}{dw} = \begin{cases} a, & |w| < 1, \\ b, & |w| > 1. \end{cases}
\] (51)

From Eq. (50), we obtain

\[
\frac{d}{dt} \left\{ \frac{1}{2} \left( \frac{x^2}{\alpha} + \frac{y^2}{\xi} + \frac{z^2}{\beta} \right) \right\} = -W(w)x^2 \leq 0, \] (52)

assuming \( a > 0 \) and \( b > 0 \). In this case, the equilibrium state \( A = \{(x,y,z,w) | x = y = z = 0, w = \text{constant}\} \) (i.e. the \( w \)-axis) is globally asymptotically stable, and Eq. (50) does not have a chaotic attractor. However, if we set \( \alpha = 4.2, \beta = -20, \xi = -1, \alpha = -2 \) and \( b = 9 \), our computer simulation of Eq. (50) gives a chaotic attractor in Fig. 12. By calculating the Lyapunov exponents from sampled time series, we found that this chaotic attractor has a positive Lyapunov exponent \( \lambda_1 \approx 0.050 \). In this case, the capacitance \( C_2 \) and the inductance \( L \) are both negative (active) and the memristor is active as shown in Fig. 13 (see [Barboza & Chua, 2008]).

The Jacobian matrix \( D \) at the equilibrium set is given by

\[
D = \begin{bmatrix} -\alpha W(w) & \alpha & 0 & 0 \\ -\xi & 0 & -\xi & 0 \\ 0 & \beta & 0 & 0 \\ 1 & 0 & 0 & 0 \end{bmatrix},
\] (53)

Fig. 12. Chaotic attractor of the fourth-order oscillator with active elements \((a = -1, b = 5)\).
and its characteristic equation is given by
\[ p^4 + \alpha W(w)p^3 + (\alpha + \beta)\xi p^2 + \alpha\beta\xi W(w)p = 0. \]  
(54)

The four eigenvalues \( \rho_i \) \( (i = 1, 2, 3, 4) \) at each equilibrium state \((0, 0, 0, w)\) can be written as
\[
\begin{align*}
\rho_{1,2} &\approx -0.189912 \pm i \ 4.37021, \\
\rho_3 &\approx 8.77982, \\
\rho_{1,2} &\approx 0.0546351 \pm i \ 4.46535, \\
\rho_3 &\approx -37.9093, \\
\rho_4 &= 0, \quad \text{for } |w| < 1, \\
\rho_4 &= 0, \quad \text{for } |w| > 1.
\end{align*}
\]  
(55)

Thus, they are characterized by an unstable saddle-focus except for the zero eigenvalue.

### 3.2. A third-order canonical memristor oscillator

Removing a capacitor (resp. an inductor) from the circuit of Fig. 7 (resp. Fig. 8), we obtain the third-order oscillator in Fig. 14 (resp. Fig. 15). Applying Kirchhoff’s circuit laws to node A and loop C of the circuit in Fig. 16, we obtain
\[
\begin{align*}
q_1 &= q_3 - q(\varphi), \\
\varphi_3 &= \varphi_4 - \varphi_1.
\end{align*}
\]  
(57)

Integrating Eq. (56) with respect to time \( t \), we obtain a set of equations which define the relation between the charge and the flux:
\[
\begin{align*}
q_1 &= \int_{-\infty}^{t} i_1(t)dt, \\
\varphi_1 &= \int_{-\infty}^{t} v_1(t)dt, \\
q_3 &= \int_{-\infty}^{t} i_3(t)dt, \\
\varphi_3 &= \int_{-\infty}^{t} v_3(t)dt, \\
q_4 &= \int_{-\infty}^{t} i_4(t)dt, \\
\varphi_4 &= \int_{-\infty}^{t} v_4(t)dt, \\
q &= \int_{-\infty}^{t} i(t)dt, \\
\varphi &= \int_{-\infty}^{t} v(t)dt = \varphi_1.
\end{align*}
\]  
(58)

Here, the symbols \( q_1, q_3, \) and \( q \) denote the charge of capacitor \( C_1 \), inductor \( L \), and the memristor, respectively, and the symbols \( \varphi_1, \varphi_3, \varphi_4 \) and \( \varphi \) denote the flux of capacitor \( C_1 \), inductor \( L \),
The term "charge" and "flux" are just names given to the definition in Eq. (58), and should not be interpreted as a physical charge or flux in the classical sense. The important concept here is that they are measurable quantities, obtained via integration.
at this equilibrium set is given by

\[ D = \begin{bmatrix} -\alpha W(z) & \alpha & 0 \\ -\xi & \beta & 0 \\ 1 & 0 & 0 \end{bmatrix}, \]  

(67)

and its characteristic equation is given by

\[ \rho^3 + (\alpha W(z) - \beta)\rho^2 + \alpha(\xi - \beta W(z))\rho = 0. \]  

(68)

If we set \( \alpha = 1, \beta = 0.1, \xi = 1, a = 0.02, \) and \( b = 2, \) then it has three eigenvalues \( \lambda_i \) \( (i = 1, 2, 3): \)

\[ \lambda_{1,2} \approx 0.04 \pm i 0.998198, \quad \lambda_3 \approx 0, \quad \text{for } |z| < 1; \]
\[ \lambda_1 \approx -1.27016, \quad \lambda_2 \approx -0.629844, \quad \lambda_3 = 0, \quad \text{for } |z| > 1. \]  

(69)

Thus, the set \( B \triangleq \{(x,y,z)|x = y = 0, |z| < 1\} \) is unstable, and the set \( C \triangleq \{(x,y,z)|x = y = 0, |z| > 1\} \) is stable. Our computer simulation shows that Eq. (65) has two distinct stable periodic attractors as shown in Fig. 17. Observe that they are odd symmetric images of each other, as expected in view of the odd-symmetric characteristic \( q = q(\varphi) \) of the memristor in Eq. (66).

Equation (65) can be transformed into the form

\[ \frac{d^2y}{dt^2} + (\alpha W(z) - \beta)\frac{dy}{dt} + \alpha(\xi - \beta W(z))y = 0, \]  

(70)

or equivalently

\[ \begin{align*}
\frac{d^2y}{dt^2} + (\alpha \beta - \beta)\frac{dy}{dt} + \alpha(\xi - \beta W(z))y & = 0, & \text{for } |z| < 1, \\
\frac{d^2y}{dt^2} + (bx - \beta)\frac{dy}{dt} + \alpha(\xi - \beta W(z))y & = 0, & \text{for } |z| > 1.
\end{align*} \]  

(71)

Thus, Eq. (65) can be interpreted as a second-order linear differential equation over the domain of the state variable \( z \) whose dynamics evolves according to \( dz/dt = x \) in Eq. (65). Furthermore, if we substitute

\[ u(t) \triangleq \int_0^t y(t)dt + c, \]
\[ z(t) = \xi^{-1}\left\{\beta u(t) - \frac{du(t)}{dt}\right\} + d, \]  

(72)

\[ 
\begin{array}{l}
\int_0^t y(t)dt + c, \\
\xi^{-1}\left\{\beta u(t) - \frac{du(t)}{dt}\right\} + d,
\end{array} \]

Fig. 17. Two periodic attractors of the third-order canonical memristor oscillator.
into Eq. (70) (c and d are constants), we would obtain the following third-order differential equation

$$\frac{d^3u}{dt^3} + \left[\alpha W \left( \xi^{-1} \left\{ \beta u(t) - \frac{du(t)}{dt} \right\} + d \right) - \beta \right] \frac{d^2u}{dt^2} + \alpha \left[ \xi - \beta W \left( \xi^{-1} \left\{ \beta u(t) - \frac{du(t)}{dt} \right\} + d \right) \right] \frac{du}{dt} = 0,$$

in terms of $u$, or equivalently

$$\frac{d^3u}{dt^3} + (\alpha \alpha - \beta) \frac{d^2u}{dt^2} + \alpha (\xi - \alpha \beta) \frac{du}{dt} = 0, \quad \text{for} \quad \xi^{-1} \left\{ \beta u(t) - \frac{du(t)}{dt} \right\} + d < 1,$$

$$\frac{d^3u}{dt^3} + (\beta \alpha - \beta) \frac{d^2u}{dt^2} + \alpha (\xi - \beta \alpha) \frac{du}{dt} = 0, \quad \text{for} \quad \xi^{-1} \left\{ \beta u(t) - \frac{du(t)}{dt} \right\} + d > 1.$$  

They can be written as

$$\frac{d}{dt} \left[ d^2u \right] + \left[ \alpha W \left( \xi^{-1} \left\{ \beta u(t) - \frac{du(t)}{dt} \right\} + d \right) - \beta \right] \frac{du}{dt} + \alpha \left[ \xi - \beta W \left( \xi^{-1} \left\{ \beta u(t) - \frac{du(t)}{dt} \right\} + d \right) \right] u = 0,$$

and

$$\frac{d}{dt} \left\{ \frac{d^2u}{dt^2} + (\alpha \alpha - \beta) \frac{du}{dt} + \alpha (\xi - \alpha \beta) u \right\} = 0, \quad \text{for} \quad \xi^{-1} \left\{ \beta u(t) - \frac{du(t)}{dt} \right\} + d < 1,$$

$$\frac{d}{dt} \left\{ \frac{d^2u}{dt^2} + (\beta \alpha - \beta) \frac{du}{dt} + \alpha (\xi - \beta \alpha) u \right\} = 0, \quad \text{for} \quad \xi^{-1} \left\{ \beta u(t) - \frac{du(t)}{dt} \right\} + d > 1.$$  

respectively. Note that $dW(z)/dz = 0$. Since the characteristic equation of Eqs. (73) and (74) have a zero-eigenvalue everywhere, and Eq. (76) can be interpreted as a second-order linear differential equation, Eq. (65) does not have a chaotic attractor, even if the circuit elements are active.

Consider next the three-element circuit in Fig. 18, obtained by short circuiting the resistor from Fig. 14 (its dual circuit is shown in Fig. 19). The dynamics of this circuit can be written as

$$\begin{align*}
\frac{dx}{dt} &= \alpha (y - W(z)x), \\
\frac{dy}{dt} &= -\xi x, \\
\frac{dz}{dt} &= x.
\end{align*}$$  

(77)

From this equation, we obtain

$$\frac{d}{dt} \left\{ \frac{1}{2} \left( \frac{x^2}{\alpha} + \frac{y^2}{\xi} \right) \right\} = -W(z)x^2 \leq 0.$$  

(78)

Hence, the z-axis is globally asymptotically stable.

From Eq. (77), we obtain

$$\frac{dy}{dt} + \xi \frac{dz}{dt} = 0.$$  

(79)

Fig. 18. A third-order circuit with a flux-controlled memristor.

Fig. 19. Dual circuit with a charge-controlled memristor.
Thus, \( y(t) \) and \( z(t) \) satisfy
\[
z(t) = \frac{-y(t) + y_0}{\xi},
\]
where \( y_0 \) is a constant. Since \( W(z) = W(y_0 - y) \), Eq. (77) can be transformed into the form
\[
\frac{d^2y}{dt^2} + \alpha W\left(\frac{y_0 - y}{\xi}\right) \frac{dy}{dt} + \alpha y = 0.
\]
Thus, Eq. (77) is equivalent to a one-parameter family of second-order differential equations. Since the minimal dimension for a continuous chaotic system is 3, Eq. (77) cannot have a chaotic attractor, even if the circuit elements are active. We will discuss this observation in Sec. 4.2.

### 3.3. A second-order canonical memristor circuit

If we remove an inductor (resp. a capacitor) from Fig. 14 (resp. Fig. 15), we would obtain the second-order circuit in Fig. 20 (resp. Fig. 21). Applying the Kirchhoff's circuit laws to the circuit in Fig. 22, we obtain

\[
i_1 = i_3 - i.
\]
Integrating Eq. (82) with respect to time \( t \), we obtain a set of equations which define a relation between the charge and the flux:
\[
q_1 = q_3 - q(\varphi),
\]
where
\[
\begin{align*}
q_1 &\triangleq \int_{-\infty}^{t} i_1(t) dt, \\
q_3 &\triangleq \int_{-\infty}^{t} i_3(t) dt, \\
q &\triangleq \int_{-\infty}^{t} i(t) dt, \\
\varphi &\triangleq \int_{-\infty}^{t} v(t) dt.
\end{align*}
\]
Here, the symbols \( q_1, q_3, \) and \( q \) denote the charge of capacitor \( C_1 \), conductance \(-G\), and the memristor, and the symbol \( \varphi \) denotes the flux of memristor, respectively. The \( \varphi - q \) characteristic curve of the memristor is given by
\[
q(\varphi) = b\varphi + 0.5(a - b)(|\varphi + 1| - |\varphi - 1|).
\]
Solving Eq. (83) for \( q_3 \), we obtain
\[
q_3 = q_1 + q(\varphi).
\]
Thus, \( q_1 \) and \( \varphi \) can be chosen as independent variables.

From Eq. (82) (or differentiating Eq. (83) with respect to time \( t \)), we obtain a set of two first-order differential equations:
\[
\begin{align*}
C_1 \frac{dv_1}{dt} &= (G - W(\varphi))v_1, \\
\frac{d\varphi}{dt} &= v_1,
\end{align*}
\]
Fig. 20. A second-order circuit with a flux-controlled memristor.

Fig. 21. Dual circuit with a charge-controlled memristor.
Fig. 22. The circuit from Fig. 20 and the $\varphi - q$ characteristic of the flux-controlled memristor defined by Eq. (85). Currents $i_1, i_3$ and voltage $v_1$ are indicated.

where

$$
\begin{align*}
\frac{dq_1}{dt} &= i_1 = C_1 \frac{dv_1}{dt}, \\
\frac{dq_3}{dt} &= i_3 = Gv_1, \\
W(\varphi) &= \frac{dq(\varphi)}{d\varphi}.
\end{align*}
$$

(88)

Note that the two kinds of independent variables are related by

$$
(q_1, \varphi) \leftrightarrow (v_1, \varphi)
$$

(89)

Thus, Eq. (87) can be recast in terms of the charge and the flux as state variables:

$$
\begin{align*}
\frac{dq_1}{dt} &= (G - W(\varphi)) \frac{q_1}{C_1}, \\
\frac{d\varphi}{dt} &= \frac{q_1}{C_1}.
\end{align*}
$$

(90)

We next study the behavior of this circuit. Equation (87) can be transformed into the form

$$
\begin{align*}
\frac{dx}{dt} &= \alpha(\beta - W(y))x, \\
\frac{dy}{dt} &= x,
\end{align*}
$$

(91)

where $x = v_1$, $y = \varphi$, $\alpha = 1/C$, $\beta = G$, and the piecewise-linear functions $q(y)$ and $W(y)$ are given by

$$
\begin{align*}
q(y) &= by + 0.5(a - b)(|y + 1| - |y - 1|), \\
W(y) &= \frac{dq(y)}{dy} = \begin{cases} a, & |y| < 1, \\
b, & |y| > 1,
\end{cases}
$$

(92)

respectively, where $a, b > 0$. The first equation of Eq. (91) can be written as

$$
\frac{dx}{dt} = \begin{cases} \alpha(\beta - a)x, & |y| < 1, \\
\alpha(\beta - b)x, & |y| > 1.
\end{cases}
$$

(93)

Thus, the solution of Eq. (93) for $|y| < 1$ and $|y| > 1$ can be expressed as

$$
x(t) = x_0 e^{\alpha(\beta-a)t},
$$

(94)

and

$$
x(t) = x_0 e^{\alpha(\beta-b)t},
$$

(95)

respectively, where $x(0) = x_0$ is the initial condition for $t = 0$. If we set $\alpha = 0.01$, $b = 0.05$. $\alpha = 1$, $\beta = 0.03$ and $e = 10$, our computer simulation shows that $x(t) \to 0$ for $t \to \infty$ as shown in Fig. 23. Thus, this second-order circuit does not oscillate.

4. Memristor-Based Chua Oscillators

In this section, we design a nonlinear oscillator by replacing "Chua's diode" with an active two-terminal circuit consisting of a negative conductance and a memristor (or an active memristor). We derive a set of differential equations from the nonlinear circuit directly.

4.1. A fourth-order memristor-based Chua oscillator

Consider Chua's oscillator in Fig. 24. If we replace Chua's diode with an active two-terminal circuit
consisting of a conductance and a flux-controlled memristor, we would obtain the circuit as in Fig. 25. The dynamics of the circuit in Fig. 25 is given by the following set of four first-order differential equations:

\[
\begin{align*}
G_1 \frac{dv_1}{dt} &= \frac{v_2 - v_1}{R} + G(v_1 - W(\varphi)v_1), \\
G_2 \frac{dv_2}{dt} &= \frac{v_1 - v_2}{R} - i, \\
L \frac{di}{dt} &= v_2 - ri, \\
\frac{d\varphi}{dt} &= v_1,
\end{align*}
\]

where
\[
q(\varphi) = b\varphi + 0.5(a - b)(|\varphi + 1| - |\varphi - 1|), \\
W(\varphi) = \frac{dq(\varphi)}{d\varphi}.
\]

Equation (96) can be transformed into the form

\[
\begin{align*}
\frac{dx}{dt} &= \alpha(y - x + \xi x - W(w)x), \\
\frac{dy}{dt} &= x - y + z, \\
\frac{dz}{dt} &= -\beta y - \gamma z, \\
\frac{dw}{dt} &= x,
\end{align*}
\]

where we set
\[
\begin{align*}
x &= v_1, & y &= v_2, & z &= -i, & w &= \varphi, \\
\alpha &= \frac{1}{C_1}, & \beta &= \frac{1}{L}, & \gamma &= \frac{r}{L}, & \xi &= G, \\
C_2 &= 1, & R &= 1,
\end{align*}
\]

and the piecewise-linear functions \(q(w)\) and \(W(w)\) are given by

\[
q(w) = bw + 0.5(a - b)(|w + 1| - |w - 1|), \\
W(w) = \begin{cases} a, & |w| < 1, \\
b, & |w| > 1, \end{cases}
\]

respectively, where \(a, b > 0\). If we set \(\alpha = 10, \beta = 13, \gamma = 0.35, \xi = 1.5, a = 0.3\) and \(b = 0.8\), our computer simulation shows that Eq. (98) has a chaotic attractor as shown in Fig. 26. By calculating the Lyapunov exponents from sampled time series, we found that this chaotic attractor has one positive Lyapunov exponent \(\lambda_1 = 0.0779\).
Fig. 25. Chua’s oscillator with a flux-controlled memristor and a negative conductance.

The equilibrium state of Eq. (98) is given by $A = \{(x, y, z, w)|x = y = z = 0, w = \text{constant}\}$, which corresponds to the $w$-axis. The Jacobian matrix $D$ at this equilibrium set is given by

$$
D = \begin{bmatrix}
\alpha(-1 + \xi - W(w)) & \alpha & 0 & 0 \\
1 & -1 & 1 & 0 \\
0 & -\beta & -\gamma & 0 \\
1 & 0 & 0 & 0
\end{bmatrix},
$$

(101)

and its four eigenvalues $\rho_i$ ($i = 1, 2, 3, 4$) can be written as

$$
\rho_{1,2} \approx -1.31104 \pm i \cdot 2.74058, \quad \rho_3 \approx 3.27207, \quad \lambda_4 = 0, \quad \text{for } |w| < 1, \\
\rho_{1,2} \approx 0.0786554 \pm i \cdot 2.84655, \quad \rho_3 \approx -4.50731, \quad \rho_4 = 0, \quad \text{for } |w| > 1.
$$

(102)

Thus, they are characterized by an unstable saddle-focus except for the zero eigenvalue.

4.2. A third-order memristor-based Chua oscillator

Consider next the Van der Pol oscillator with Chua’s diode as illustrated in Fig. 27. If we replace Chua’s diode with a two-terminal circuit consisting of a conductance and a flux-controlled memristor, we would obtain the circuit shown in Fig. 28. The dynamics of this circuit is given by

$$
\begin{align*}
C \frac{dv}{dt} &= -i - W(\varphi)v + Gv, \\
L \frac{di}{dt} &= v, \\
\frac{d\varphi}{dt} &= v,
\end{align*}
$$

(103)

where

$$
W(\varphi) = \frac{dq(\varphi)}{d\varphi}, \\
q(\varphi) = b\varphi + 0.5(a - b)(|\varphi + 1| - |\varphi - 1|).
$$

(104)

Equation (103) can be transformed into the form

$$
\begin{align*}
\frac{dx}{dt} &= \alpha(-y - W(z)x + \gamma x), \\
\frac{dy}{dt} &= \beta x, \\
\frac{dz}{dt} &= x.
\end{align*}
$$

(105)
where $x = v$, $y = i$, $z = \varphi$, $\alpha = 1/C$, $\beta = 1/L$, $\gamma = G$, and the piecewise-linear functions $q(z)$ and $W(z)$ are given by

$$q(z) = bz + 0.5(a - b)(|z + 1| - |z - 1|),$$

$$W(z) = \begin{cases} a, & |z| < 1, \\ b, & |z| > 1, \end{cases}$$

respectively, where $a, b > 0$. From Eq. (105), we obtain

$$\frac{dy}{dt} - \beta \frac{dz}{dt} = 0.$$  

Thus, $y(t)$ and $z(t)$ satisfy

$$z(t) = \frac{y(t) + c}{\beta},$$

respectively.
Fig. 27. Van der Pol oscillator.

Fig. 28. A third-order oscillator with a flux-controlled memristor and a negative conductance.

where \( c \) is constant. Since \( W(z) = W((y + c)/\beta) \), Eq. (105) can be transformed into the form

\[
\frac{d^2 y}{dt^2} + \alpha \left\{ W\left(\frac{y + c}{\beta}\right) - \gamma \right\} \frac{dy}{dt} + \alpha \beta y = 0,
\]

or equivalently

\[
\begin{align*}
\frac{d^2 y}{dt^2} + \alpha(a - \gamma) \frac{dy}{dt} + \alpha \beta y &= 0, \quad |z| < 1, \\
\frac{d^2 y}{dt^2} + \alpha(b - \gamma) \frac{dy}{dt} + \alpha \beta y &= 0, \quad |z| > 1.
\end{align*}
\]

Thus, Eq. (105) is equivalent to a one-parameter family of second-order differential equations, parametrized by the constant \( "c" \), via Eq. (108). Since the minimal dimension for a continuous chaotic system is 3, Eq. (105) cannot have a chaotic attractor, even if the circuit elements are active. If we set \( \alpha = 2, \gamma = 0.3, \beta = 1, a = 0.1 \) and \( b = 0.5 \), our computer simulation shows that Eq. (105) has two periodic attractors as shown in Fig. 29. Observe that these two limit cycles are odd-symmetric images of each other, as expected. The equilibrium state of Eq. (105) is given by

\[
A = \{(x, y, z)|x = y = 0, z = \text{constant}\},
\]

which corresponds to the z-axis. The Jacobian matrix \( D \) at this equilibrium set is given by

\[
D = \begin{bmatrix}
\alpha(\gamma - W(z)) & -\alpha & 0 \\
\beta & 0 & 0 \\
1 & 0 & 0
\end{bmatrix}.
\]

Its characteristic equation and eigenvalues \( \lambda_i (i = 1, 2, 3) \) can be written as

\[
\begin{cases}
\rho(\rho^2 + \alpha(a - \gamma)\rho + \alpha \beta) = 0, & |z| < 1, \\
\rho(\rho^2 + \alpha(b - \gamma)\rho + \alpha \beta) = 0, & |z| > 1,
\end{cases}
\]

and

\[
\begin{cases}
\lambda_{1,2} = 0.2 \pm i 1.4, & \lambda_3 = 0, \quad \text{for } |z| < 1, \\
\lambda_{1,2} = -0.2 \pm i 1.4, & \lambda_3 = 0, \quad \text{for } |z| > 1,
\end{cases}
\]

respectively. Thus, the equilibrium set is unstable if \( |z| < 1 \), and stable if \( |z| > 1 \).

4.3. A second-order memristor-based circuit

Consider again the Van der Pol oscillator with the voltage-controlled Chua’s diode from [Barboza & Chua, 2008], as illustrated in Fig. 27. If we let the capacitance \( C \to 0 \), we would obtain the relaxation oscillator shown in Fig. 30, which exhibits a jump behavior [Chua, 1969]. Furthermore, by replacing Chua’s diode in Fig. 30 with a two-terminal circuit consisting of a conductance and a flux-controlled memristor, we obtain the circuit of Fig. 31. The dynamics of the circuit in Fig. 31 is given by

\[
\begin{align*}
i &= (G - W(\varphi))v, \\
L \frac{di}{dt} &= v, \\
\frac{d\varphi}{dt} &= v,
\end{align*}
\]

where

\[
W(\varphi) = \frac{dq(\varphi)}{d\varphi},
\]

\[
q(\varphi) = b\varphi + 0.5(a - b) \times (|\varphi + 1| - |\varphi - 1|).
\]
Equation (114) can be written as

\[
\begin{align*}
    y &= (\gamma - W(z))x, \\
    \frac{dy}{dt} &= \beta x, \\
    \frac{dz}{dt} &= x, \\
\end{align*}
\]

(116)

where \( x = v, y = i, z = \varphi, \beta = 1/L, G = \gamma \). From Eq. (116), we obtain

\[
\frac{dy}{dt} - \beta \frac{dz}{dt} = 0.
\]

(117)

Thus, \( y(t) \) and \( z(t) \) satisfy

\[
y(t) - \beta z(t) = c,
\]

(118)

Fig. 30. A relaxation oscillator where the \( v_D - i_D \) curve of Chua's diode is given by Fig. 15 of [Barboza & Chua, 2008].
where \( c \) is a constant. From Eq. (116), we obtain
\[
y = (\gamma - W(z))x = (\gamma - W(z)) \frac{dz}{dt}.
\]  
(119)

We can interpret Eq. (119) as a one-parameter family of first-order differential equations, namely,
\[
\frac{dz}{dt} = \frac{y}{\gamma - W(z)} = \frac{\beta z + c}{\gamma - W(z)}.
\]

(120)

The solution of Eq. (120) for \(|z| < 1\) and \(|z| > 1\) can be expressed as
\[
z(t) = de^{-\alpha t} - \frac{c}{\beta},
\]
(121)

and
\[
z(t) = de^{-\alpha t} + \frac{c}{\beta},
\]
(122)

respectively, where \( c \) and \( d \) are constants.

If we replace the piecewise-linear function of the memristor by a smooth cubic function, namely
\[
q(z) = \begin{cases} 
\frac{z^3}{3}, & \text{for } |z| < 1, \\
W(z) = z^2, & \text{for } |z| > 1.
\end{cases}
\]

(123)

we would obtain
\[
\frac{dz}{dt} = \frac{\beta z + c}{\gamma - z^2}.
\]

(124)

If we set \( \gamma = 1, \beta = 1 \) and \( c = 1 \), the correct solution of Eq. (124) is given by
\[
z(t) = 1 + \sqrt{2(e - t)},
\]
(125)

where \( e \) is a constant, and shown in Fig. 32. Our computer simulation shows that Eq. (124) exhibits the incorrect irregular oscillation shown in Fig. 33. This erroneous computer-generated solution is caused by the numerical integration error at \( z = \pm 1 \).

4.4. First-order memristor-based circuit

Consider the circuit in Fig. 34, which consists of a current source \( J \) and a two-terminal circuit consisting of a conductance and a flux-controlled memristor. The circuit equation of Fig. 34 can be written as
\[
\int (J + Gv) dt = q(\varphi),
\]

(126)

where \( q(\varphi) \) denotes the characteristic of the memristor. Differentiating Eq. (126) with respect to time \( t \), we obtain
\[
\frac{d\varphi}{dt} = \frac{J + Gv}{W(\varphi)},
\]

(127)
where
\[
W(\varphi) = \frac{dq(\varphi)}{d\varphi}.  \tag{128}
\]
From the first equation of Eq. (127), we obtain
\[
v = \frac{J}{W(\varphi) - G} = \frac{d\varphi}{dt}. \tag{129}
\]
Thus, Eq. (127) can be written as
\[
\frac{dx}{dt} = \frac{e}{W(x) - \beta},  \tag{130}
\]
where \(x = \varphi, e = J, \beta = G\), and the functions \(q(x)\) and \(W(x)\) are defined by
\[
q(x) = \begin{cases} 0.05x^2, & x \geq 0, \\ 0.05x, & x < 0, \end{cases} \tag{131}
\]
\[
W(x) = \frac{dq(x)}{dx} = \begin{cases} 0.1x, & x \geq 0, \\ 0.05, & x < 0. \end{cases}
\]
In this case, \(q(x)\) is not a piecewise-linear function. If we set \(\beta = 0.3\) and \(e = 1\), our computer simulation shows that Eq. (130) exhibits an irregular oscillation as shown in Fig. 35. This computer generated solution is erroneous, and is caused by the numerical integration error at \(x = 3\), since Eq. (130) can be recast into the form
\[
\frac{dx}{dt} = -\frac{10}{x - 3}, \quad \text{for } x > 0, \tag{132}
\]
it follows that \(|dx/dt|\) tends to infinity when \(x \to 3\). The exact solution of Eq. (132) is given analytically by
\[
x = 3 \pm \sqrt{2(C - 10t)}, \tag{133}
\]
where \(C\) is some constant, and does not exhibit any oscillations, as shown in Fig. 36. Note that solution of Eq. (133) does not exist for \(t > C/10\), implying that a more realistic circuit model of the physical circuit is needed [Chua et al., 1987].
5. Conclusion

We have derived several memristor-based nonlinear oscillators from Chua's oscillators. These oscillators have many interesting oscillation properties and rich nonlinear dynamics. We conclude therefore that the memristors are useful for designing nonlinear oscillators.
